Temperature: The Antarctic Peninsula is located in the west of the Antarctic and has an average annual temperature of about 0°C. Antarctic sea ice is formed through wind blown sea ice and snowfall. The Antarctic is usually above the melting point of ice and can be up to 4m thick, covering up to 70% of the continental surface. On the east side of the Antarctic the Antarctic ice sheet is limited to the region of the Ross ice shelf and the Weddell sea. At the Southern tip of South America, the Antarctic peninsula divides the continent into two. South America dominates the entire continent from the western edge of the eastern ice sheet, with the Falkland Islands in the west, to the western edge of the ice sheet at the South Pole. This is the most prominent feature of the continent and the western edge is the easternmost limit of the ice sheet. The Antarctic Peninsula is a part of the Antarctic. The Antarctic continent is the largest and southernmost continent in the world. It is located between 60S and 70S latitude. About half the area is covered with ice sheets and ice caps. The ice sheets are subjected to frequent temperature changes. The primary component of the surface of the Antarctic is a massive ice sheet. The Peninsula has a surface of about 50,000 miles and is one of the ice free areas of the continent. The base of the peninsula is the Antarctic plateau, a very high plateau
